ABSTRACT

The Data-Enhanced Investigations for Climate Change Education (DICCE) project, funded by NASA, is providing dedicated climate data portals in the NASA Giovanni data system for the use of teachers and students. The central content of the DICCE-Giovanni data portals is a reduced set of climate-relevant data parameters drawn from the available Giovanni data sets, with accessible meanings, such as surface temperature, precipitation amount, snow cover, phytoplankton chlorophyll concentration, vegetation indices, and aerosol optical depth. Information resources explain the significance of the data to climate research, how to interpret climate data trends, and address uncertainties in both data visualizations and the interpretation of data plotting output. "How-to" videos and plotting tips facilitate the utilization of the data portals, so that teachers can create problem-based projects based on actual satellite observational data. The use of satellite data in a problem-based framework enhances the relevance and immediacy of the project content to the student, improves their understanding of Earth climate system interrelationships, and also improves pattern recognition, math skills, and interpretation of data representations.

COMPONENTS OF DICCE-GIOVANNI

The NASA Goddard Earth Sciences Data and Information Services Center (GES DISC) hosts the Giovanni data visualization and analysis system, which in turn hosts the current Giovanni data portals for the DICCE Project. There are currently two DICCE data portals:

- > DICCE-Giovanni Basic Climate (Monthly) Data
- classed as *Ocean, Atmosphere, Energy, and Land* data types
- > DICCE-Giovanni Daily Data
- with daily temporal resolution data products from the *MODIS, AIRS, OMI, and TRMM instruments** of NASA Earth-observing missions

The GES DISC also hosts related informational content to support the data products and available analysis options in the Giovanni system. This content is found on the **DICCE Resources Page** and includes:

- ➤ DICCE-Giovanni Extended Help
- Climate Data Regional Trend Guides
- > DICCE-Giovanni Plotting Tips
- DICCE-Giovanni Troubleshooting Guide
- DICCE-Giovanni Instructional Videos

In the current third year of the project, as DICCE teachers are utilizing these resources to create instructional projects on climate change, these informational resources will be enhanced with additional videos, demonstrating plotting tips and providing more examples of how to use the data analysis options to investigate climate change topics using Earth observational data from NASA missions and climate/weather models.

The DICCE-Giovanni (DICCE-G) components are illustrated in the next panels of this poster, followed by an example of how a climate change problem can be constructed and addressed with the DICCE-Giovanni components.

*

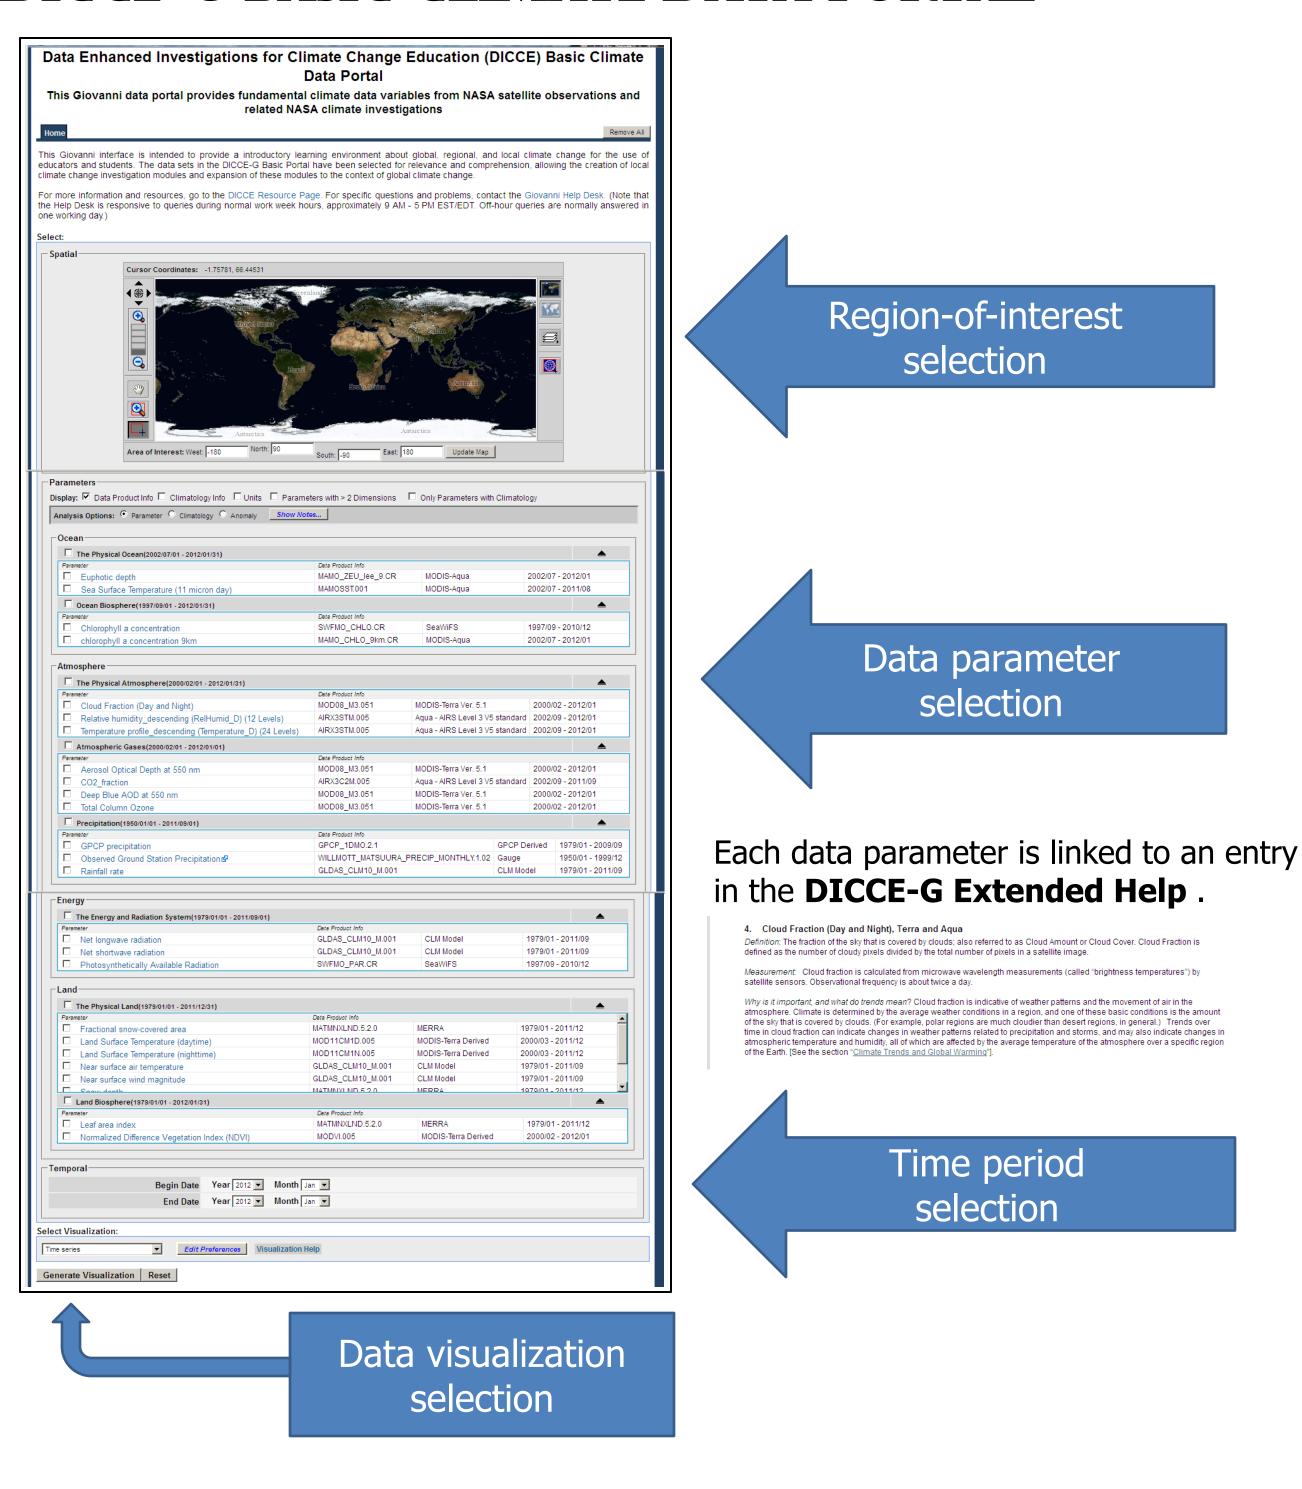

MODIS – Moderate Resolution Imaging Spectro-radiometer

AIRS – Atmospheric Infrared Sounder

OMI – Ozone Measuring Instrument

TRMM – Tropical Rainfall Measuring Mission

DICCE-G BASIC CLIMATE DATA PORTAL

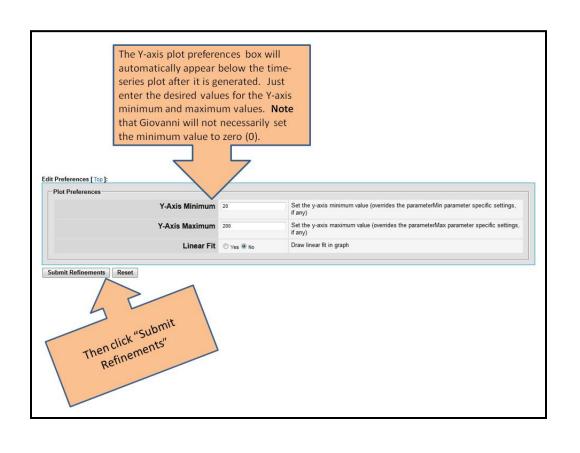

DICCE-G CLIMATE DATA TREND GUIDES

		Means		Could this trend be an effect of climate warming?	Could this trend also be contributing to more climate warming in the region?	Could this trend also be contributing to less climate warming in the region?
Higher values of	Aerosol Optical Depth or Deep Blue Aerosol Optical Depth	More aerosols in the air (also known as particulate matter)	More human induced emissions of particulate matter from motor vehicles, factories, power plants, airplanes, etc, or from volcanic eruptions	Unlikely	Unlikely	Yes. Though they are harmful in large doses to human health, aerosols have the opposite effect on incoming solar radiation than do greenhouse gases. Aerosols scatter and absorb outgoing solar radiation rather than reflect them back to the earth. This is known as the "dimming" effect, which it the opposite of the warming effect from greenhouse gases.
Lower values of	Aerosol Optical Depth or Deep Blue Aerosol Optical Depth		Diminishing pollution of particulate matter from human sources or diminishing effects from prior volcanic eruptions	Unlikely	Yes. Less aerosols in the air means less absorption of outgoing longwave radiation, which hence counteracts trapping of heat in the lower atmosphere by greenhouse gases.	No, only if there were human induced sources of the aerosols and the diminishing aerosol tren is paralleled by less carbon dioxide being emitted. These datrends could be evidence that people are taking steps to decrease emissions from source that emit both greenhouse gases (such as carbon dioxide) and aerosols. Examples would be power plants and motor vehicles which emit both.

This page of the *Atmospheric Gases Trend Guide* discusses how to interpret increasing and decreasing trends of Aerosol Optical Depth.
DICCE resources emphasize the importance of examining data trends over time to detect and quantify climate change.

DICCE-G INSTRUCTIONAL "HOW-TO" VIDEOS

Version 2.0 of the DICCE-G Instructional Videos consists of narrated Animated slide presentations demonstrating basic Giovanni operations. Plotting tip videos and screen capture videos of actual Giovanni analyses will be added to the library this year.

WATER RESOURCES & SNOW TRENDS IN NEW MEXICO: USING DICCE-GIOVANNI FOR PROBLEM-BASED LEARNING

Snow pack conditions in the northern mountains of New Mexico are of continuing concern, due to the fact that much of the state depends on runoff from the snow pack to provide water for populated areas to the south for both agriculture and public use. Over the past few years, persistent drought conditions have reduced the snow pack in these northern mountains.

One potential contributing factor may be lower sea surface temperatures (SST) observed in the Pacific Ocean off of southern California, Baja California, and the Gulf of California. Moisture from the ocean is transported inland via the monsoonal flow to provide both rain and snow to New Mexico. Cooler winter SSTs lead to less ocean water evaporation and weaker storm systems.

Pacific Ocean study region

Cursor Coordinates: -137.78809, 20.00293

Whiteless and the state of Interest: West: -128

North: 34

South: 21

East: -106

Update Map

Two data products from the Modern Era Retrospective-analysis for Research and Applications (MERRA) project, fractional snow cover and snow mass, indicate a trend of reduced snow pack in this region of the New Mexico mountains.

MODIS-Aqua SSTs for the Pacific Ocean southwest of New Mexico indicate a declining trend of winter SSTs over the past nine years.

These data thus provide an answerable problem relating potential cause-and-effect observations in the Earth's climate system. This particular problem could be used to introduce many different climate concepts, including the water cycle, El Niño-, La Niña, atmospheric circulation, and the importance of the cryosphere; or to test understanding of these concepts.

After creating the visualizations with DICCE-G, teachers can then utilize the DICCE Learning Environment (described in other presentations at this meeting) to create problem-based learning projects for classroom instruction.

Advanced students or classes could also be invited to utilize DICCE-G resources to address climate change problems in an investigative learning mode.

Acknowledgment: Funding for the Data-Enhanced Investigations for Climate Change Education Project is provided by NASA Grant #NNX10AT54A, administered out of the Langley Research Center's NASA Innovations In Climate Education (NICE) program.
